 1. An attacker intercepts the following ciphertext (hex encoded):
     20814804c1767293b99f1d9cab3bc3e7 ac1e37bfb15599e5f40eef805488281d
     He knows that the plaintext is the ASCII encoding of the message "Pay Bob 100$" (excluding the
     quotes). He also knows that the cipher used is CBC encryption with a random IV using AES as the
     underlying block cipher.
     Show that the attacker can change the ciphertext so that it will decrypt to "Pay Bob 500$". What is
     the resulting ciphertext (hex encoded)?
     This shows that CBC provides no integrity.
       20814804c1767293bd9f1d9cab3bc3e7 ac1e37bfb15599e5f40eef805488281d
         Correct
              You got it!
2. Let (E, {\cal D}) be an encryption system with key space {\cal K}, message
                                                                                                                                 0 / 1 point
     space \{0,1\}^n and ciphertext space \{0,1\}^s . Suppose (E,D)
     provides authenticated encryption. Which of the following systems
     provide authenticated encryption: (as usual, we use || to denote
     string concatenation)
     \longrightarrow E'(k,m)=ig(E(k,m),\ E(k,m)ig) and
            D'(k, (c_1, c_2)) = D(k, c_1)
          This should not be selected
               This system does not provide ciphertext integrity. The attacker
               can query for E'(k,0^n) to obtain (c_1,c_2) . It then outputs
               (c_1,0^s) and wins the ciphertext integrity game.
     E'((k_1, k_2), m) = E(k_2, E(k_1, m)) and
           D'ig((k_1,k_2),\ cig) = \left\{egin{array}{ll} D(k_1,\ D(k_2,c)) & 	ext{if } D(k_2,c) 
eq \perp \ & 	ext{otherwise} \end{array}
ight.
        Correct
              (E^\prime,D^\prime) provides authenticated encryption because an attack on (E^\prime,D^\prime)
               gives an attack on ({\cal E},{\cal D}) . It's an interesting exercise to work out
               the ciphertext integrity attack on (E,\mathcal{D}) given a ciphertext integrity
               attacker on (E',D').
     \ensuremath{ \ensuremath{ igsigma} } E'(k,m) = ig( E(k,m), \; H(m) \; ig) and
            D'(k,\ (c,h)\ ) = \left\{ egin{aligned} D(k,c) & 	ext{if } H(D(k,c)) = h \ ot & 	ext{otherwise} \end{aligned} 
ight.
          (here H is some collision resistant hash function)
          This should not be selected
              This system is not CPA secure because H(m) leaks information about
               the message in the ciphertext.
     igwedge E'(k,m) = igl[ c \leftarrow E(k,m), 	ext{ output } (c,c) \, igr] and
           D'(k,\ (c_1,c_2)\ )=\left\{egin{array}{ll} D(k,c_1) & 	ext{if } c_1=c_2 \ ot & 	ext{otherwise} \end{array}
ight.
         ✓ Correct
              (E^{\prime},D^{\prime}) provides authenticated encryption because an attack on (E^{\prime},D^{\prime})
               directly gives an attack on (E,D).
                                                                                                                                1/1 point
3. If you need to build an application that needs to encrypt multiple
     messages using a single key, what encryption
     method should you use? (for now, we ignore the question of key generation
     and management)
     implement MAC-then-Encrypt yourself
     use a standard implementation of CBC encryption with
          a random IV.
     implement Encrypt-and-MAC yourself

    use a standard implementation of one of the authenticated

          encryption modes GCM, CCM, EAX or OCB.
         Correct
4. Let (E,\mathcal{D}) be a symmetric encryption system with message space M (think
                                                                                                                                 1/1 point
     of M as only consisting for short messages, say 32 bytes).
     Define the following MAC (S,V) for messages in M:
      S(k,m) := E(k,m) \;\;\; ; \;\;\; V(k,m,t) := \left\{ egin{array}{ll} 1 & 	ext{if } D(k,t) = m \\ 0 & 	ext{otherwise} \end{array} 
ight.
     What is the property that the encryption system ({\cal E},{\cal D}) needs to satisfy
     for this MAC system to be secure?

    authenticated encryption

     semantic security under a deterministic chosen plaintext attack

    semantic security

     semantic security under a chosen plaintext attack
         Correct
              Indeed, authenticated encryption implies ciphertext
                 integrity which prevents existential
                       forgery under a chosen message attack.
In <u>Key Derivation</u> we discussed how to derive session keys
     from a shared secret. The problem is what to do when the shared
     secret is non-uniform. In this question we show that using a PRF with
     a non-uniform key may result in non-uniform values. This shows that
     session keys cannot be derived by directly using a non-uniform
     secret as a key in a PRF. Instead, one has to use a key derivation
     function like HKDF.
     Suppose k is a non-uniform secret key sampled from the key space \{0,1\}^{256}.
     In particular, k is sampled uniformly from the set of all keys whose most significant
     128 bits are all 0. In other words, k is chosen uniformly from a small subset of the key space. More
     precisely,
    \text{for all } c \in \{0,1\}^{256}: \quad \Pr[k=c] = \left\{ \begin{matrix} 1/2^{128} & \text{if } \mathrm{MSB}_{128}(c) = 0^{128} \\ 0 & \text{otherwise} \end{matrix} \right.
    Let F(k,x) be a secure PRF with input space \{0,1\}^{256} . Which
     of the following is a secure PRF when the key k is uniform in the
     key space \{0,1\}^{256} , but is insecure when the key is sampled from the \emph{non-uniform}
     distribution described above?
    F'(k,x) = egin{cases} F(k,x) & 	ext{if MSB}_{128}(k) 
eq 0^{128} \\ 0^{256} & 	ext{otherwise} \end{cases}
    egin{aligned} igcap F'(k,x) = egin{cases} F(k,x) & 	ext{if MSB}_{128}(k) = 0^{128} \ 0^{256} & 	ext{otherwise} \end{cases}
    F'(k,x) = \begin{cases} F(k,x) & 	ext{if MSB}_{128}(k) \neq 1^{128} \\ 0^{256} & 	ext{otherwise} \end{cases}
    F'(k,x) = egin{cases} F(k,x) & 	ext{if MSB}_{128}(k) = 0^{128} \ 1^{256} & 	ext{otherwise} \end{cases}
              F^{\prime}(k,x) is a secure PRF because for a uniform key k the
              probability that \mathrm{MSB}_{128}(k)=0^{128} is negligible.
              However, for the *non-uniform* key k this PRF always outputs 0
              and is therefore completely insecure. This PRF cannot be used as a
              key derivation function for the distribution of keys described in the problem.
6. In what settings is it acceptable to use deterministic authenticated
     encryption (DAE) like SIV?
     when messages are chosen at random from a large enough space so that
          messages are unlikely to repeat.
     when a fixed message is repeatedly encrypted using a single key.

    to individually encrypt many packets in a voice conversation with a single key.

     to encrypt many records in a database with a single key when the same record may repeat multiple
         ✓ Correct
               Deterministic encryption is safe to use when the message/key pair
               is never used more than once.
7. Let E(k,x) be a secure block cipher. Consider the following
                                                                                                                                 1/1 point
     tweakable block cipher:
       E'((k_1,k_2),t,x) = E(k_1,x) \bigoplus E(k_2,t).
     Is this tweakable block cipher secure?
     \ \odot no because for t \neq t' we have
          E'((k_1,k_2),t,0) \bigoplus E'((k_1,k_2),t,1) = E'((k_1,k_2),t',0) \bigoplus E'((k_1,k_2),t',1)
     \bigcirc no because for t 
eq t' we have
          E'((k_1,k_2),t,0) \bigoplus E'((k_1,k_2),t',1) = E'((k_1,k_2),t',1) \bigoplus E'((k_1,k_2),t',0)
     On because for x \neq x' and t \neq t' we have
          E'((k_1,k_2),t,x) \bigoplus E'((k_1,k_2),t',x) = E'((k_1,k_2),t,x') \bigoplus E'((k_1,k_2),t',x)
     On because for x \neq x' we have
          E'((k_1,k_2),0,x) \bigoplus E'((k_1,k_2),0,x) = E'((k_1,k_2),0,x') \bigoplus E'((k_1,k_2),0,x')
     \bigcirc yes, it is secure assuming E is a secure block cipher.
         Correct
              since this relation holds, an attacker can make 4 queries to E^\prime
              and distinguish E^\prime from a random collection of one-to-one functions.
                                                                                                                                 1/1 point
8. In Format Preserving Encryption we discussed format preserving encryption
     which is a PRP on a domain \{0,\ldots,s-1\} for some pre-specified
     value of s.
     Recall that the construction we presented worked in two steps,
     where the second step worked by iterating the PRP until the output
     fell into the set \{0,\ldots,s-1\}.
     Suppose we try to build a format preserving credit card encryption
     system from AES using *only* the second step. That is, we start with
     a PRP with domain \{0,1\}^{128} from which we want to build a PRP
     with domain 10^{16}\,. If we only used step (2), how many iterations of
     AES would be needed in expectation for each evaluation of the PRP
     with domain 10^{16}?
    O 2
     \odot 2^{128}/10^{16} \approx 3.4 \times 10^{22}
    \bigcirc 10^{16}/2^{128}
    \bigcirc 2<sup>128</sup>
              On every iteration we have a probability of 10^{16} \, / 2^{128} of falling
              into the set \{0,\dots,10^{16}\} and therefore in expectation we
              will need 2^{128}/10^{16} iterations. This should explain why
              step (1) is needed.
9. Let (E,D) be a secure tweakable block cipher.
                                                                                                                                 1/1 point
     Define the following MAC (S,V):
     S(k,m) := E(k,m,0) ; V(k,m, \text{tag}) := \begin{cases} 1 & \text{if } E(k,m,0) = \text{tag} \\ 0 & \text{otherwise} \end{cases}
     In other words, the message m is used as the tweak and the plaintext given to E is always set to 0. \,
```

Is this MAC secure?

Correct

O no

12288

O 48

0 1024

16384

Correct

256

it depends on the tweakable block cipher.

A tweakable block cipher is indistinguishable from a

collection of random permutations. The chosen message attack on the

permutations in the family. But that tells the attacker nothing about

10. In CBC Padding Attacks we discussed padding oracle attacks. These chosen-ciphertext attacks can

Consider a system that implements MAC-then-encrypt where encryption is done using CBC with a random IV using AES as the block cipher. Suppose the system is vulnerable to a padding oracle attack. An attacker intercepts a 64-byte ciphertext \mathcal{C} (the first 16 bytes of \mathcal{C} are the IV and the remaining 48 bytes are the encrypted payload). How many chosen ciphertext queries would the attacker need *in the worst case* in order to decrypt the entire 48 byte payload? Recall that padding

1/1 point

Correct. Padding oracle attacks decrypt the payload one byte at a time. For each byte the attacker needs no more than 256 guesses in the worst case. Since there are 48 bytes total, the number queries needed is 256 imes 48 = 1228.

MAC gives the attacker the image of $\boldsymbol{0}$ under a number of the

the image of $\boldsymbol{0}$ under some other member of the family.

break poor implementations of MAC-then-encrypt.

oracle attacks decrypt the payload one byte at a time.
